Super Mario 64's unreadable plaque, decoded: it says "Eternal Star / We hope so"

For almost 30 years, players have squinted at a blurry little plaque in the castle courtyard of Super Mario 64. The famous reading, "L is real 2401", launched the legend that Luigi was hidden somewhere in the game. He wasn't. The plaque says something else: "Eternal Star / We hope so", typed in a font Adobe released in 1990.

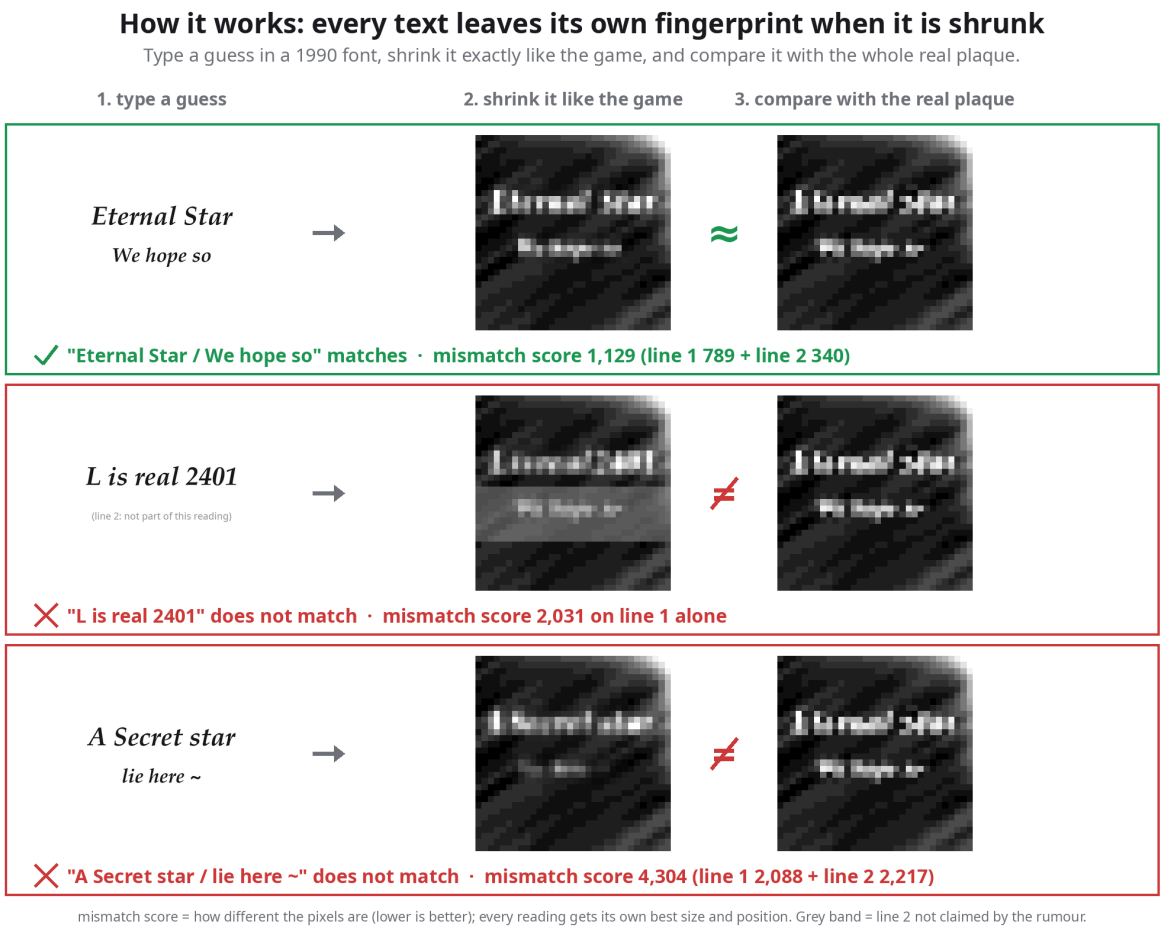

The short version

- **Nobody can read the plaque.** The game stores it as one tiny picture, 32 by 32 pixels, and the letters are 3 to 5 pixels tall.
- **So I stopped trying to read it and rebuilt it instead.** I typed guesses in fonts from the 1990s, shrank them exactly the way the game did, and laid them over the real plaque. One text fits: **"Eternal Star / We hope so"**.
- **Then I tried to break my own answer.** 1.2 million rival first words. A blind test with 50 secret words: all 50 found. About 5,000 fonts. Every reading proposed since the 1990s, scored the same way: "L is real 2401" fits 2.6 times worse, "A Secret star / lie here ~" almost 4 times worse.

The mystery

Super Mario 64 came out in 1996. A stone statue holding a star stands in the courtyard of Princess Peach's castle, and on it sits a small engraved plaque, a smear of grey pixels that no player could ever read. Fans read "L is real 2401" into it, and from that grew one of gaming's most stubborn rumours: that Mario's brother Luigi could be unlocked somewhere in the game. Kids hunted for him for years. In 1998, Nintendo of America answered a fan's letter and said the plaque was a joke by the developers with no meaning. What it actually says, Nintendo never revealed.

How it works

Shrink a word to a few pixels and the letters vanish. Not completely, though. **Every text leaves behind its own pattern of grey blocks, a fingerprint.** You can't read a fingerprint, but you can take the fingerprints of your own guesses and check which one matches.

The picture shows it for the whole plaque and three readings. "Eternal Star / We hope so" fits both lines. "L is real 2401" never said what line 2 reads, so I leave line 2 out of its score, and it still fails on line 1. "A Secret star / lie here ~" fails on both lines.

I did exactly that. Type a guess in a 1990s font, about 26 pixels tall, on a small digital canvas. Shrink it to 32 by 32 pixels the way a 1996 texture artist would have. Lay it on the plaque's stone background. A computer then counts how far every pixel is from the real plaque and adds it all up into a **mismatch score**: the lower, the better. I ran this for millions of texts, thousands of fonts and every common way of shrinking a picture.

Why I am confident

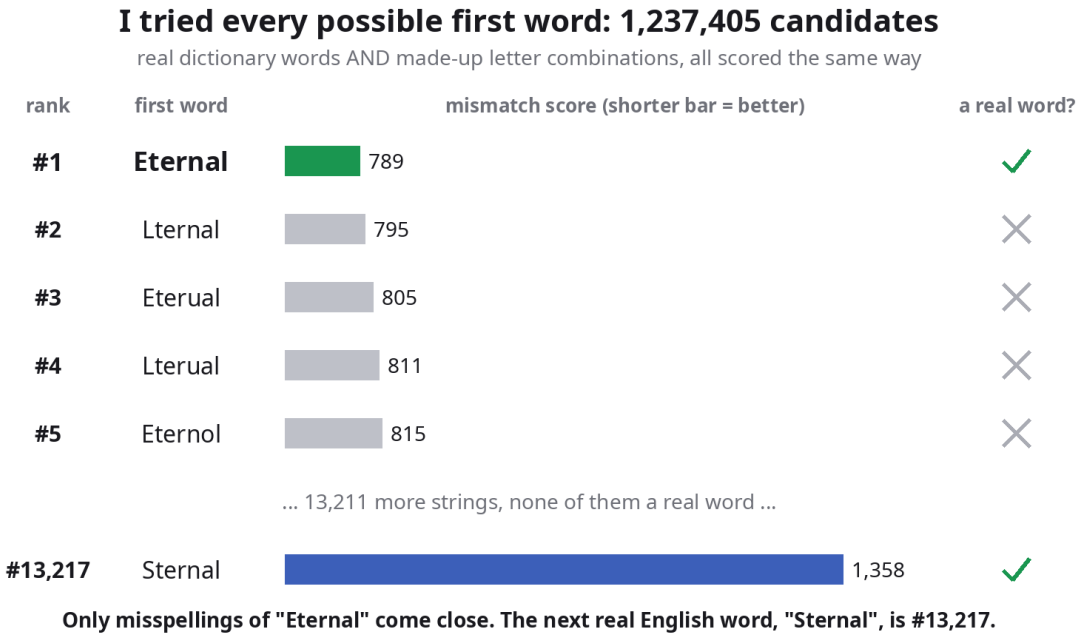

1. The reconstruction is almost a copy. The plaque uses 32 shades of grey. Inside the letters, my version is off by about one shade on average. Look at the first picture again: the real plaque and the rebuilt one are hard to tell apart. Seven pixels refuse to match in every version I tried, and they look like the artist touched them up by hand.

2. Every bright blob sits under a letter.

Draw the outlines of “Eternal Star / We hope so” over the untouched game pixels and each bright smudge lands inside a letter, down to the dot-like tail of the “p” in “hope”. The rivals don’t line up. “L is real 2401” only gets close when the computer squeezes out its word spaces, and “A Secret star / lie here ~” misses on both lines.

3. “Eternal” beats every other first word I could think of, and 1.2 million I couldn’t.

I didn’t hand-pick the rivals. A program assembled 1,237,405 candidates letter by letter: dictionary words, but also gibberish like “Lternal” and “Eterual”. “Eternal” won. The runners-up are all misspellings of “Eternal”, and the next real English word, “Sternal”, only shows up at place 13,217.

4. Line 2 says “We hope so”, and “hope” is certain.

Line 2: a blind search through 17,700 English words

the computer was not told any words. Its 8 best answers (lower score = better):

#1	**We hope so**	362	**real words**
#2	We **hope** he	363	real words
#3	We **hope** as	369	real words
#4	We **hope** hr	372	not real words
#5	Bk **hope** us	372	not real words
#6	Bk **hope** hr	374	not real words
#7	We **hope** us	374	real words
#8	We **hope** or	375	real words

"hope" is in every single answer. The best one is "We hope so".

The last word is the least certain: "he" and "as" are close behind, but only "We hope so" is a natural sentence.

For the second line, the computer combined 17,700 common English words with no hints. “hope” sits in all eight of its best answers. “We hope so” comes first. Only the last word wobbles: “he” and “as” are close, but they don’t make a sentence.

5. A blind test: I hid 50 secret words, and the method found all 50.

Blind test: I hid 50 secret words in the plaque. The method found all 50.

Random English words, locked away before decoding, each written into the real plaque as "<word> Star"

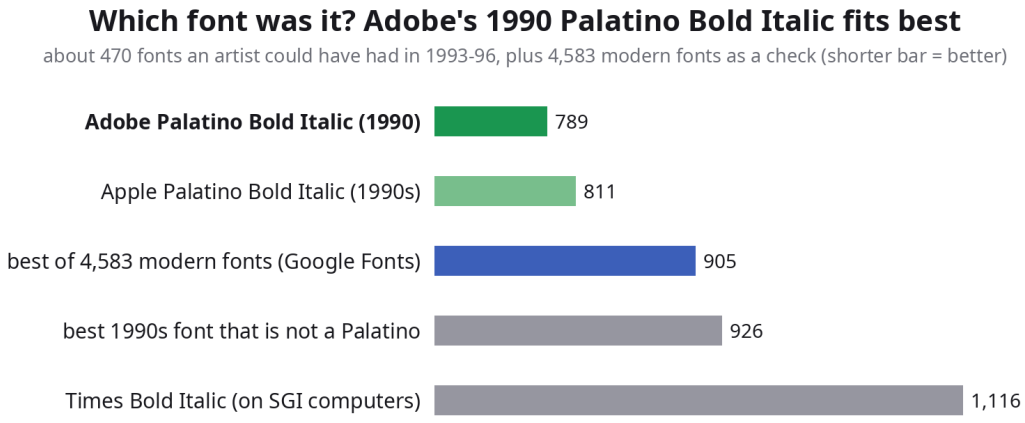

✓ Brace	✓ Lanai	✓ Preface	✓ Relying	✓ Striped
✓ Duration	✓ Anytime	✓ Gratis	✓ Intimate	✓ Pairwise
✓ Impaired	✓ Those	✓ Frequent	✓ Variance	✓ Sealed
✓ Inserted	✓ Internet	✓ Samba	✓ Affine	✓ Spelled
✓ Labels	✓ Occurs	✓ Member	✓ Glyph	✓ Expat
✓ Revert	✓ Entirely	✓ Accept	✓ Prepared	✓ Stating
✓ Broad	✓ Opening	✓ Noticed	✓ Tolerate	✓ Stencil
✓ Cycles	✓ Broadly	✓ Model	✓ Grand	✓ Bloom
✓ Scanner	✓ Await	✓ Harness	✓ Superior	✓ Probe
✓ Enclose	✓ Applying	✓ Adding	✓ Plastic	✓ Cleaner

In every case the hidden word was the best-fitting real word (50 of 50).

In 38 of 50 it was #1 of about 1.2 million strings; in the others only a misspelling (like "Dnration") scored slightly better.

Sceptics have one obvious objection. “You found ’Eternal’ because you went looking for it.” Fair enough. So I let the computer draw 50 random English words, from “Brace” to “Harness”, sealed them away before decoding, and wrote each one into the real plaque in place of “Eternal”. Then the method searched blind. Every hidden word came back as the best-fitting real word. In 38 cases it even beat all 1.2 million strings; in the other 12, only a misspelling like “Dnration” (for “Duration”) edged ahead.

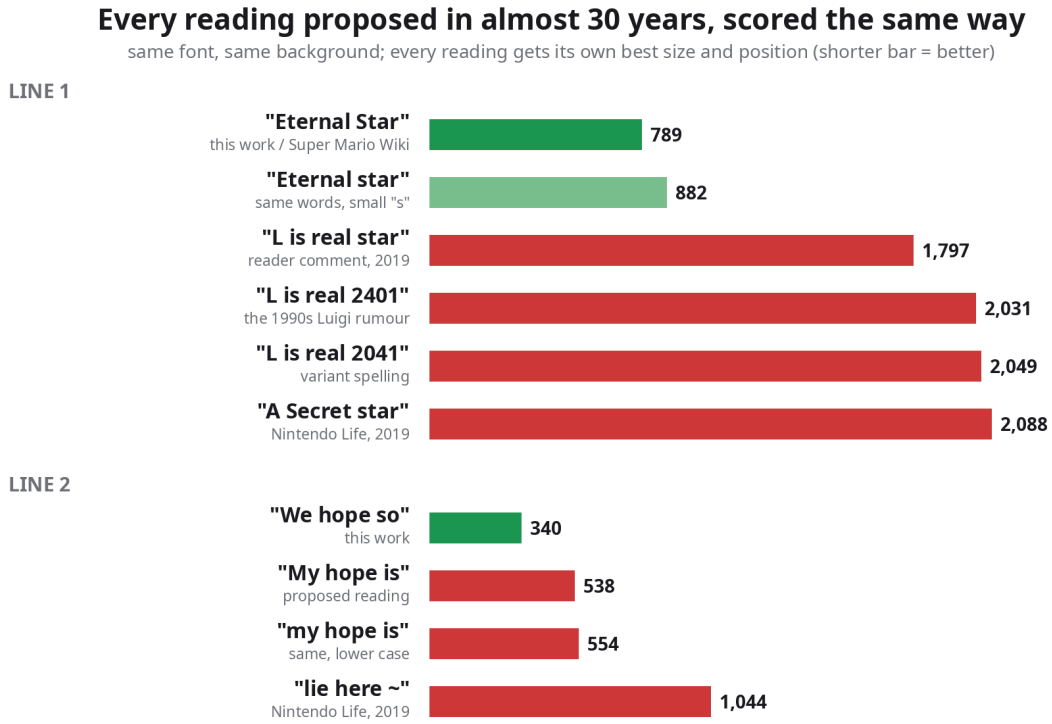

6. The font fits, and the artist could have had it.

The exact Adobe file could be installed on the SGI workstations the game was made on (1995).

I collected about 470 fonts that a texture artist could have owned in 1993 to 1996: from Silicon Graphics computers, Macs, Windows PCs, Photoshop, Illustrator, CorelDRAW. Adobe's 1990 Palatino Bold Italic fits best, and the twelve best designs are all versions of Palatino or its close relatives. Palatino itself is a classic, drawn around 1950. I also tested 4,583 modern fonts from Google's library. None comes close. And the exact Adobe file was within reach: SGI's 1995 operating system could install fonts from Adobe's "Type On Call" CD, and that CD's Palatino Bold Italic has letter measurements identical to my file, byte for byte. Nintendo built Super Mario 64 on SGI workstations.

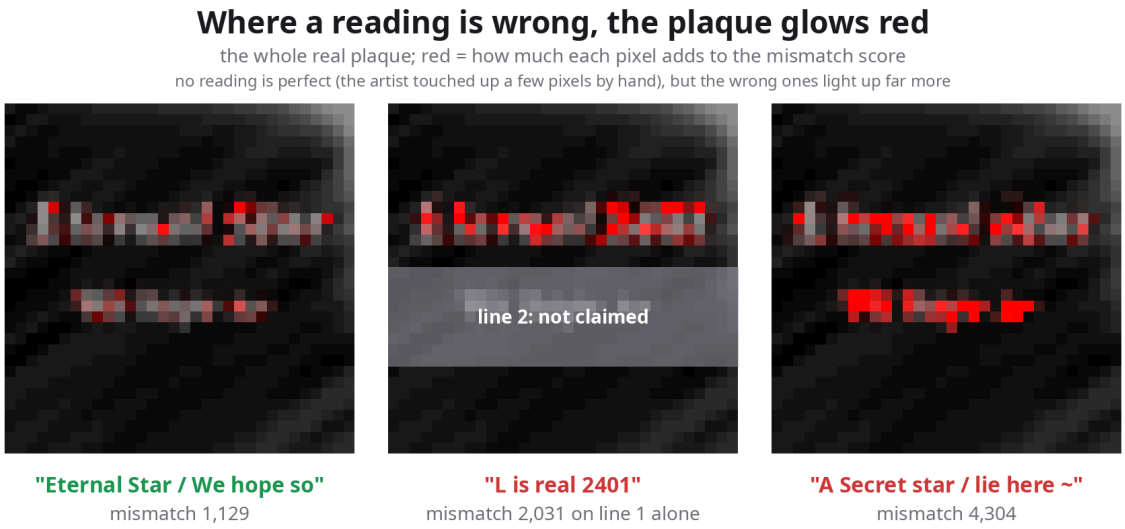

7. Every reading proposed in almost 30 years loses.

Whole plaque: "A Secret star / lie here ~" scores 4,304, "Eternal Star / We hope so" 1,129 (3.8 times better).

I collected every reading I could find: the 1990s rumour "L is real 2401" and its "2041" variant, "L is real star" from a 2019 reader comment, "A Secret star / lie here ~" from Nintendo Life in 2019, and

“My hope is” for line 2. Each one got its own best letter size and position. None comes close. “L is real 2401” scores 2,031 against 789 for “Eternal Star”, 2.6 times worse, and the whole of “A Secret star / lie here ~” scores 4,304 against 1,129.

The red map shows where. The famous rumour needs a short capital “L”, a tiny “is”, gaps between the words and four wide digits. The plaque shows one long, evenly inked first word with no gap after its capital. On line 2, “lie here ~” predicts letters where the plaque is dark and misses the bright blobs of “hope”. The pixels light up wherever the shapes disagree.

How sure am I, word by word?

Word	How sure	Why
Eternal	●●●●● very sure	#1 of 1.2 million candidates; a blind search finds it on its own
Star	●●●●○ sure	#1 of 27,122 words (capital “S” or small “s” can’t be told apart)
We	●●●●○ sure	the best real word with the right shape
hope	●●●●● very sure	#1 of 12,556 words; turns up in every search
so	●●●○○ fairly sure	the best real ending, but “or”, “us” and “he” are not far behind

What does it mean?

A Japanese team made Super Mario 64, and the two lines read like English written by Japanese developers: a name, then a wish, the way Japanese memorial plaques are often worded. “Eternal Star” is 永遠の星 (eien no hoshi). “We hope so” is a stock school-English way of saying そうであってほしい, “we hope it is so”. Put together: *an eternal star, and we hope it truly is one.* That’s a playful line for a statue that holds a star, and it squares with Nintendo’s 1998 answer that the plaque was a joke by the developers. This part is my interpretation. The reading itself comes from the pixels alone.

What this does not prove

- **This is not a Nintendo document.** The answer comes from the pixels. Only the original developers can confirm it 100 %.

- **At this size, some misspelled non-words fit almost as well** as the real words, “Lternal” for example. The pixels fix the shape of the letters. Ordinary English decides between a real word and nonsense.
- **“so” is the weakest word.**

Everything is public: the code, every result file and a 52-page report. Anyone can rerun it. And anyone who thinks I’m wrong can take the challenge: beat my score with a better reading, or hide a secret word and try to fool the decoder. Every attempt goes on a public leaderboard.

Questions you might have

Is this just AI upscaling? No. No image AI and no upscaler touched the plaque, so nothing was invented. The program types text, shrinks it and counts pixel differences, like a very patient person with a magnifier and a ruler. Same input, same result, every time. I used an AI coding assistant (Claude) to write the program; the program itself contains no AI.

What’s new compared with earlier attempts? Earlier readings, including the 2019 one in Nintendo Life, came from reading the pixels by eye, from TV photos or from upscaled images, and upscalers make up detail. I never tried to read the pixels. I tested every candidate against them and gave each one a score, the earlier readings included.

Has Nintendo confirmed it? No. The only official word is that 1998 letter calling the plaque a developers’ joke. I would welcome a comment from anyone who worked on the game.

Didn’t the 2020 Nintendo leak settle this? No. The leaked files showed that Luigi existed in early development, which revived the rumour, but they say nothing about the plaque’s text. I used no leaked material at all. Everything here comes from the plaque in the game as sold.

Could the plaque be in Japanese? No. A Japanese team made the game, so I tested Japanese text too: kana and kanji, in Japanese fonts, scored the same way. It fits far worse than English. Japanese characters are square blocks of even height, while the plaque shows the uneven rhythm of Latin italic letters: tall capitals and ascenders like the “E”, “t”, “l” and “S”, with small letters in between.

Is the plaque the same in every version? Yes. It is byte-for-byte identical in the Japanese, American and European releases and in the 1997 “Shindou” rumble edition. Nintendo never changed it.

Why is it so blurry? The whole plaque is a single 32 × 32 picture, 1,024 pixels, stretched over a stone slab. The Nintendo 64 had only 4 KB of memory for the textures it draws at any moment, so small pictures were the rule.

Where does the stone background come from? From a 1990s stock-photo CD. The Render96 fan community traced it to image SC003 of the Japanese “Sozaijiten” collection, a photo of brushed metal. The artist rotated it by about 30 degrees and reworked it heavily; I confirmed the direction of the brush marks.

Could it still say “L is real 2401”? Not by these pixels. Even with its own best settings and its word spaces squeezed out, it fits 2.6 times worse than “Eternal Star”. It predicts wide digits where the plaque shows italic letters, and the plaque has no gap where “L is” needs one.

How can I check this myself? Everything is on GitHub: the code, every result file, the 52-page report. You can even run the blind test with your own secret words.

Who did this? The independent retro gaming channel mochi64. No connection to Nintendo.

Fact sheet

Game	Super Mario 64 (Nintendo, 1996), castle courtyard, plaque on the star statue
The plaque in the game	one picture of 32 × 32 pixels, letters 3–5 pixels tall
Most likely text	**Eternal Star / We hope so**
Font	Palatino Bold Italic, most likely Adobe's version from 1990
First-word candidates tested	1,237,405 (real words and made-up letter strings)
Blind test	50 of 50 secret words found as the best real word
Fonts compared	about 470 from the 1990s, plus 4,583 modern fonts
Earlier readings	"L is real 2401" 2,031 vs. 789 for "Eternal Star" (2.6 × worse); "A Secret star / lie here ~" 4,304 vs. 1,129 (3.8 ×)
Same in all versions?	yes, byte-identical in the Japanese, US, European and Shindou releases
Code, data, full report	github.com/supermochi64/sm64-plaque-decode (free and open)
Made by	the retro gaming channel mochi64, with the help of AI coding tools (Claude by Anthropic)
